    idx = 0; /// segtree index [0, n-1]
    dfs(root); build_hld(root);
    /// initialize data structure
}

```

### 1.3 Mo's

```

/// Complexity:  $O(|N+Q| \cdot \sqrt{|N|} \cdot |ADD/DEL|)$ 
/// Tested: Not yet
/// Requires add(), delete() and get_ans()
struct query {
    int l, r, idx;
    query(int l, int r, int idx) : l(l), r(r), idx(idx) {}
};
int S; /// s = sqrt(n)
bool cmp(query a, query b) {
    if (a.l/S != b.l/S) return a.l/S < b.l/S;
    return a.r > b.r;
}
S = sqrt(n); /// n = size of array
sort(q.begin(), q.end(), cmp);
int l = 0, r = -1;
for (int i = 0; i < q.size(); ++i) {
    while (r < q[i].r) add(++r);
    while (l > q[i].l) add(--l);
    while (r > q[i].r) del(r--);
    while (l < q[i].l) del(l++);
    ans[q[i].idx] = get_ans();
}

```

### 1.4 Order statistics

```

#include <ext/pb_ds/assoc_container.hpp>
#include <ext/pb_ds/tree_policy.hpp>
using namespace __gnu_pbds;
typedef tree<int, null_type, less<int>, rb_tree_tag,

```

```

tree_order_statistics_node_update> ordered_set;
//methods
tree.find_by_order(k) //returns pointer to the k-th smallest element
tree.order_of_key(x) //returns how many elements are smaller than x
//if element does not exist
tree.end() == tree.find_by_order(k) //true

```

### 1.5 Persistent segment tree

```

/// Complexity:  $O(|N| \cdot \log|N|)$ 
/// Tested: Not yet
struct node {
    node *left, *right;
    int v;
    node() : left(this), right(this), v(0) {}
    node(node *left, node *right, int v) :
        left(left), right(right), v(v) {}
    node* update(int l, int r, int x, int value) {
        if (l == r) return new node(nullptr, nullptr, v + value);

```

## 5.6 Integral

- Simpsons rule:  $\int_a^b f(x)dx \approx \frac{b-a}{6}[f(a) + 4f(\frac{a+b}{2}) + f(b)]$
- Arc length:  $s = \int_a^b \sqrt{1 + [f'(x)]^2}dx$
- Area of a surface of revolution:  $A = 2\pi \int_a^b f(x)\sqrt{1 + [f'(x)]^2}dx$
- Volume of a solid of revolution:  $V = \pi \int_a^b f(x)^2 dx$
- Note: In case of multiple functions such as  $g(x)$   $h(x)$  for a solid of revolution then  $f(x) = g(x) - h(x)$
- $f'(x) \approx \frac{f(x+h)-f(x-h)}{2h}$
- $f'(x) \approx \frac{f(x-2h)-8f(x-h)+8f(x+h)-f(x+2h)}{12h}$
- $f''(x) \approx \frac{f(x+h)-2f(x)+f(x-h)}{h^2}$

## 6.6 Maximum flows with edge demands

We construct a new graph  $G'=(V',E')$  from  $G$  by adding new source and target vertices  $s'$  and  $t'$ , adding edges from  $s'$  to each vertex in  $V$ , adding edges from each vertex in  $V$  to  $t'$ , and finally adding an edge from  $t$  to  $s$ . As follows:

- $D = \sum_{u \rightarrow v \in E} d(u \rightarrow v)$
- For each vertex  $v \in V$ , we set  $c'(s' \rightarrow v) = \sum_{u \in V} d(u \rightarrow v)$  and  $c'(v \rightarrow t') = \sum_{w \in V} d(v \rightarrow w)$
- For each edge  $u \rightarrow v \in E$ , we set  $c'(u \rightarrow v) = c(u \rightarrow v) - d(u \rightarrow v)$
- Finally, we set  $c'(t \rightarrow s) = \infty$
- Note: When there is no  $s, t$  you can work without them.

In  $G'$ , the total capacity out of  $s'$  and the total capacity into  $t'$  are both equal to  $D$ . We call a flow with value exactly  $D$  a saturating flow, since it saturates all the edges leaving  $s'$  or entering  $t'$ . If  $G'$  has a saturating flow, it must be a maximum flow, so we can find it using any max-flow algorithm.

Once we've found a feasible  $(s, t)$ -flow in  $G$ , we can transform it into a maximum flow using an augmenting-path algorithm, but with one small change. To ensure that every flow we consider is feasible, we must redefine the residual capacity of an edge as follows:

$$\begin{aligned}
 &c(u \rightarrow v) - f(u \rightarrow v), \text{ for original edges} \\
 &f(v \rightarrow u) - d(v \rightarrow u), \text{ for residual edges} \\
 &0, \text{ otherwise}
 \end{aligned}$$

## 6.7 Push relabel
